More headaches from installing Apache 2.2 on Vista x64 today.

The Apache connector is bad. First, see Adobe's fairly pathetic technote [here](#).

Install the new wsconfig.jar as they describe. If the remainder of the technote works for you, I hate you. If not, I'll save you a few hours of swearing.

Go to your cfusionmx7\runtime\lib folder and copy the .bat file that's attached to this message (download link below). Of course, you will have to update your paths such that they're correct (you can do that in notepad).

You can also enter commands directly in the command prompt if you are looking for extra stress today.

When all's said and done, apache should hopefully restart and serve up .CFM files correctly.
